GENOVA DIAGNOSTICS

Objectives

- Early detection of insulin resistance (IR)
  - Look for history, signs and symptoms of insulin resistance
  - Attempt to clinically assess the stage of IR
  - Find the underlying root cause or causes
- Diagnose appropriately IR, IGT, Pre-DM, DM-II
  - Clinical exam
  - Laboratory measures
  - If you cannot diagnose but have a high index of suspicion for IR, treat as insulin resistant
- Individualize Treatment
  - Diet and lifestyle
  - Address gut microbiota
  - Nutraceuticals / pharmaceuticals

Which Came First?

Disordered Fat Storage and Mobilization in the Pathogenesis of Insulin Resistance and Type 2 Diabetes

Resistance, and Type 2 Diabetes
A. Hormone-sensitive lipase (HSL) and insulin suppression of lipolysis
B. Adipose tissue uptake and intracellular esterification of fatty acids
C. Total fat mass and regional fat depots
D. Fat diversion from adipose to nonadipose tissue
E. Abnormal fatty acid metabolism in skeletal muscle
F. Potential abnormalities of intestinal fatty acid uptake
G. Protective role of leptin and adiponectin against

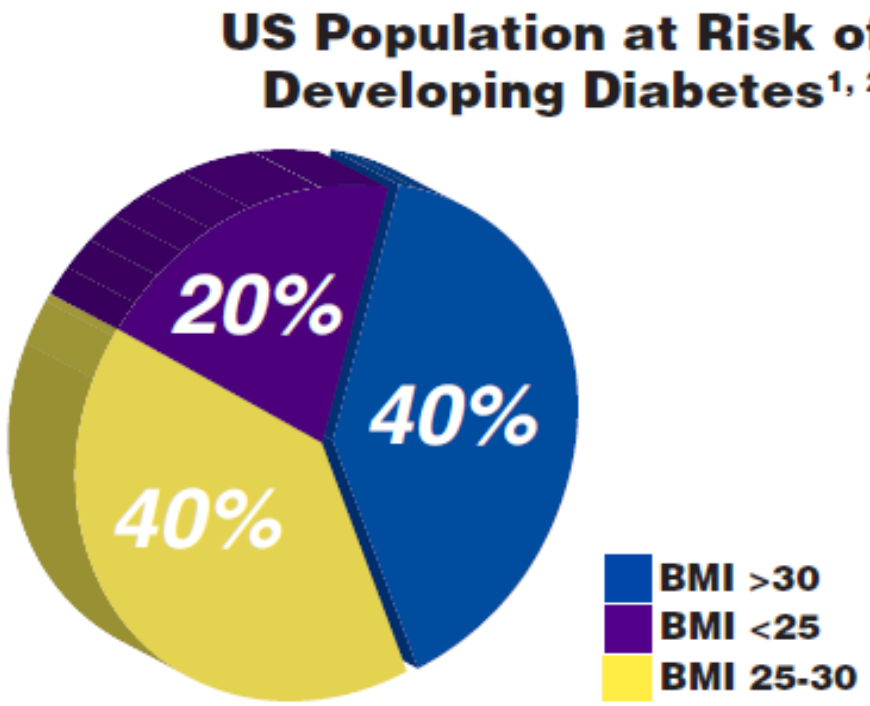
Type 2 Diabetes
A. The contribution of *de novo* lipogenesis to elevated VLDL production
B. Contribution of hepatic cytosolic triglyceride stores to VLDL overproduction and fatty liver infiltration (nonalcoholic steatohepatitis)
C. Hepatic lipoprotein remnant uptake also contributes to VLDL production
D. The role of resistance to insulin action in the hepatocyte and chronic hyperinsulinemia per se in

The sequence of events leading to whole body insulin resistance is first a positive net energy balance; then triglyceride accumulation in "fat-buffering" adipose tissue becomes limited by the development of adipose tissue insulin resistance.

This results in diversion of energy substrates to nonadipose tissue, which in turn leads to a complex array of metabolic abnormalities characteristic of insulin-resistant states and type 2 diabetes.

Lewis GF, et al. *Endocr Rev*. 2002 Apr;23(2):201-29.

According to the CDC, only **40%** of the risk of developing diabetes occurs in people who are **obese**!



How do we find the **other 60%** of the people at risk for developing diabetes who are NOT obese?

Body Mass Index

SCIENTIFIC REPORTS

OPEN

Body mass index trajectory patterns and changes in visceral fat and glucose metabolism before the onset of type 2 diabetes

Received: 26 July 2016

identified in adults developing and not developing diabetes, respectively. Among adults developing diabetes, 47.3% were classified as "medium BMI" (n = 895), and had increased mean BMI within the obesity category before diagnosis. The "low BMI" group (38.4%, n = 726) had an initial mean BMI of 21.9 kg/m^2, and demonstrated small weight gain. The "high BMI" group (n = 271) were severely obese and showed greater increase in BMI until diagnosis. All groups which developed diabetes showed absolute and/or relative increase in visceral fat and impaired β-cell compensation for insulin resistance. All groups not developing diabetes showed measured variables were relatively stable during observation. These data suggest that visceral fat gain may induce β-cell failure in compensation for insulin resistance, resulting in diabetes regardless of obesity level.

Diabetes is of growing concern worldwide. In particular, East Asia is experiencing a rapidly emerging diabetes epidemic and accounts for more than 25% of the global diabetic population[1]. Obesity is a major risk factor for

"These data suggest that visceral fat gain may induce β-cell failure in compensation for insulin resistance, resulting in diabetes regardless of obesity level."

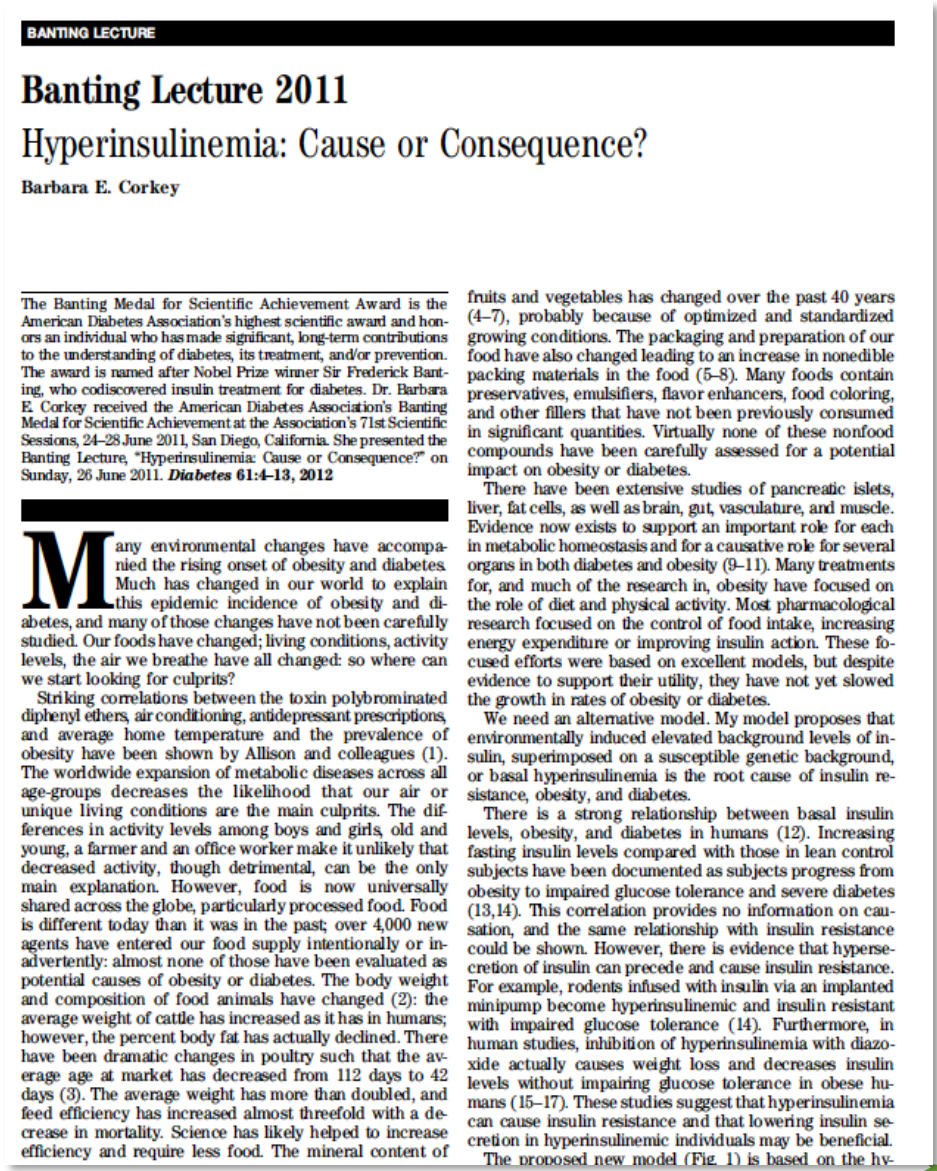
Kuwahara K, et al. *Sci Rep*. 2017 Mar 7;7:43521.

Other Theories

"Insulin resistance starts in the Beta cell with hyperinsulinemia causing insulin resistance. The initial cause is damage to the Beta cell."

– Barbara Corkey

Dr. Corkey initially observed that mono-oleoylglycerol, iron, and saccharin may all be common dietary ingredients that are capable of producing hyperinsulinemia. Then in 2014 she published a much more extensive list of food additives and toxins leading to insulin resistance



BANTING LECTURE

Banting Lecture 2011

Hyperinsulinemia: Cause or Consequence?

Barbara E. Corkey

The Banting Medal for Scientific Achievement Award is the American Diabetes Association's highest scientific award and honors an individual who has made significant, long-term contributions to the understanding of diabetes, its treatment, and/or prevention. The award is named after Nobel Prize winner Sir Frederick Banting, who codiscovered insulin treatment for diabetes. Dr. Barbara E. Corkey received the American Diabetes Association's Banting Medal for Scientific Achievement at the Association's 71st Scientific Sessions, 24–28 June 2011, San Diego, California. She presented the Banting Lecture, "Hyperinsulinemia: Cause or Consequence?" on Sunday, 26 June 2011. *Diabetes* **61:4–13, 2012**

Many environmental changes have accompanied the rising onset of obesity and diabetes. Much has changed in our world to explain this epidemic incidence of obesity and diabetes, and many of those changes have not been carefully studied. Our foods have changed; living conditions, activity levels, the air we breathe have all changed: so where can we start looking for culprits?

Striking correlations between the toxin polybrominated diphenyl ethers, air conditioning, antidepressant prescriptions, and average home temperature and the prevalence of obesity have been shown by Allison and colleagues (1). The worldwide expansion of metabolic diseases across all age-groups decreases the likelihood that our air or unique living conditions are the main culprits. The differences in activity levels among boys and girls, old and young, a farmer and an office worker make it unlikely that decreased activity, though detrimental, can be the only main explanation. However, food is now universally shared across the globe, particularly processed food. Food is different today than it was in the past; over 4,000 new agents have entered our food supply intentionally or inadvertently: almost none of those have been evaluated as potential causes of obesity or diabetes. The body weight and composition of food animals have changed (2): the average weight of cattle has increased as it has in humans; however, the percent body fat has actually declined. There have been dramatic changes in poultry such that the average age at market has decreased from 112 days to 42 days (3). The average weight has more than doubled, and feed efficiency has increased almost threefold with a decrease in mortality. Science has likely helped to increase efficiency and require less food. The mineral content of fruits and vegetables has changed over the past 40 years (4–7), probably because of optimized and standardized growing conditions. The packaging and preparation of our food have also changed leading to an increase in nonedible packing materials in the food (5–8). Many foods contain preservatives, emulsifiers, flavor enhancers, food coloring, and other fillers that have not been previously consumed in significant quantities. Virtually none of these nonfood compounds have been carefully assessed for a potential impact on obesity or diabetes.

There have been extensive studies of pancreatic islets, liver, fat cells, as well as brain, gut, vasculature, and muscle. Evidence now exists to support an important role for each in metabolic homeostasis and for a causative role for several organs in both diabetes and obesity (9–11). Many treatments for, and much of the research in, obesity have focused on the role of diet and physical activity. Most pharmacological research focused on the control of food intake, increasing energy expenditure or improving insulin action. These focused efforts were based on excellent models, but despite evidence to support their utility, they have not yet slowed the growth in rates of obesity or diabetes.

We need an alternative model. My model proposes that environmentally induced elevated background levels of insulin, superimposed on a susceptible genetic background, or basal hyperinsulinemia is the root cause of insulin resistance, obesity, and diabetes.

There is a strong relationship between basal insulin levels, obesity, and diabetes in humans (12). Increasing fasting insulin levels compared with those in lean control subjects have been documented as subjects progress from obesity to impaired glucose tolerance and severe diabetes (13,14). This correlation provides no information on causation, and the same relationship with insulin resistance could be shown. However, there is evidence that hypersecretion of insulin can precede and cause insulin resistance. For example, rodents infused with insulin via an implanted minipump become hyperinsulinemic and insulin resistant with impaired glucose tolerance (14). Furthermore, in human studies, inhibition of hyperinsulinemia with diazoxide actually causes weight loss and decreases insulin levels without impairing glucose tolerance in obese humans (15–17). These studies suggest that hyperinsulinemia can cause insulin resistance and that lowering insulin secretion in hyperinsulinemic individuals may be beneficial.

The proposed new model (Fig. 1) is based on the hy-

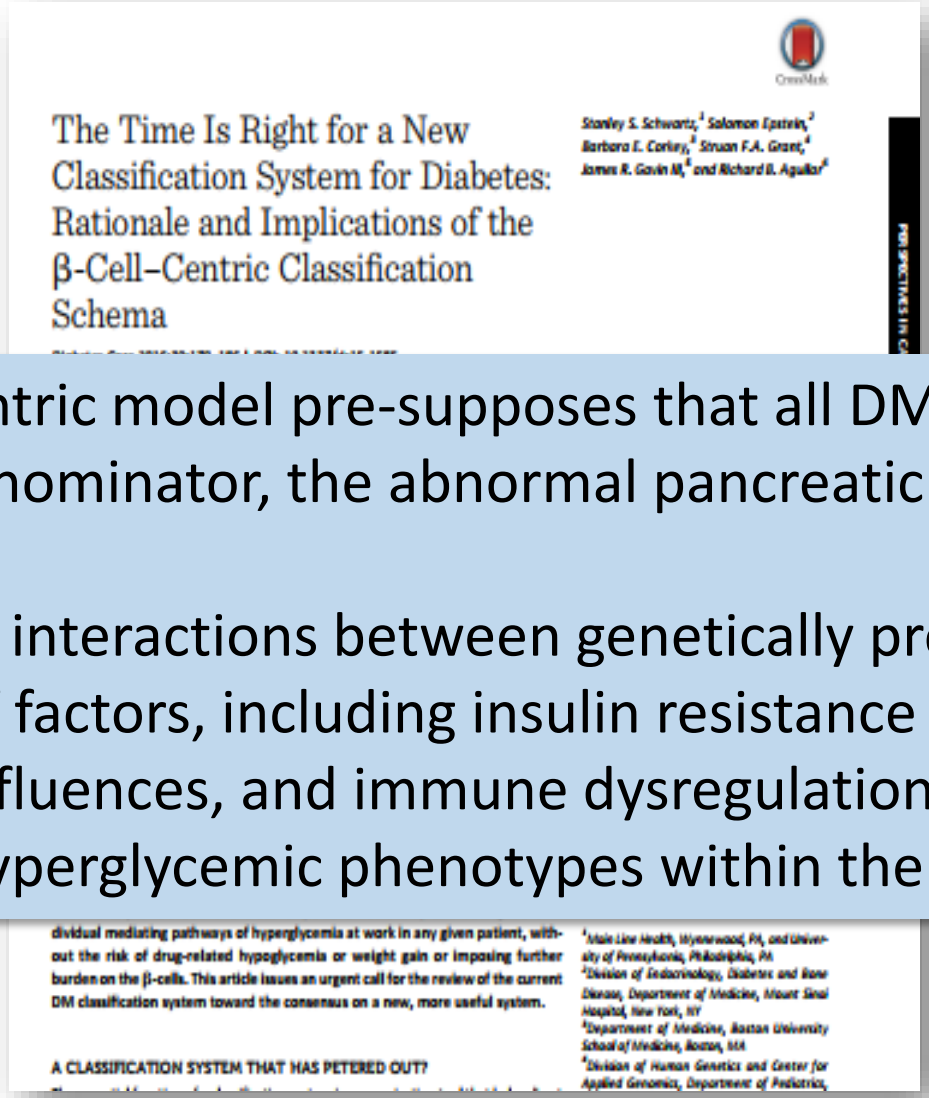
New Classification System for Diabetes?



The Time Is Right for a New Classification System for Diabetes: Rationale and Implications of the β-Cell–Centric Classification Schema

Stanley S. Schwartz,[1] Salomon Epstein,[2] Barbara E. Corkey,[3] Struan F.A. Grant,[4] James R. Gavin III,[5] and Richard B. Aguilar[6]

dividual mediating pathways of hyperglycemia at work in any given patient, without the risk of drug-related hypoglycemia or weight gain or imposing further burden on the β-cells. This article issues an urgent call for the review of the current DM classification system toward the consensus on a new, more useful system.

A CLASSIFICATION SYSTEM THAT HAS PETERED OUT?

The beta-cell–centric model pre-supposes that all DM originates from a final common denominator, the abnormal pancreatic b-cell.

It recognizes that interactions between genetically predisposed b-cells with a number of factors, including insulin resistance (IR), susceptibility to environmental influences, and immune dysregulation/inflammation, lead to the range of hyperglycemic phenotypes within the spectrum of DM.

many of these contaminants have been found to dysregulate endocrine function, insulin signaling, and/or adipocyte function. Although momentum for the chemical obesogen hypothesis is growing, supportive, evidence-based research is lacking. In order to identify noxious synthetic compounds in the environment out of the thousands of chemicals that are currently in use, tools and models from toxicology should be adopted (e.g., functional high throughput screening methods, zebrafish-based assays). Finally, mechanistic insight into obesogen-induced effects will be helpful in elucidating their role in the obesity epidemic as well as preventing and reversing their effects.

"Healthy approaches to beverage and dietary consumption should be recommended and hopefully established in infancy, with the aim of preventing negative effects on general health in later childhood and adulthood.

and hopefully established in infancy, with the aim of preventing negative effects on general health in later childhood and adulthood.

Sugars added to foods during processing, preparation or at table, sweeten food and beverage taste, improve their palatability and are used to preserve foods and to confer property such as viscosity, texture and color. They provide sensory enhancement to foods and promote enjoyment but, although they may be required in some clinical situations, they are not a necessary component of the diet in healthy children. In addition to its role in carious disease, for which there is moderate evidence of a direct correlation, increasing attention has been paid to how dietary sugars affect obesity, Type 2 diabetes mellitus, and cardiometabolic and kidney diseases

aciduric bacteria (Streptococci mutans and Lactobacilli especially), which decrease salivary and plaque pH. Otherwise, a diet lower in sugars and fermentable carbohydrates and high in calcium-rich cheese may favour remineralisation.

Studies have confirmed the direct correlation between intake of dietary sugars and carious disease throughout the course of life. The type of food (solid or beverage), exposure time, and frequency of eating also play an important role in the development of carious disease.

Since the first studies, additional factors, besides the diet, have been recognised in the aetiopathogenesis of carious disease that include salivary

Author information

Abstract

Non-caloric artificial sweeteners (NAS) are among the most widely used food additives worldwide, regularly consumed by lean and obese individuals alike. NAS consumption is considered safe and beneficial owing to their low caloric content, yet supporting scientific data remain sparse and controversial. Here we demonstrate that consumption of commonly used NAS formulations drives the development of glucose intolerance through induction of compositional and functional alterations to the intestinal microbiota. These NAS-mediated deleterious metabolic effects are abrogated by antibiotic treatment, and are fully transferrable to germ-free mice upon faecal transplantation of microbiota configurations from NAS-consuming mice, or of microbiota anaerobically incubated in the presence of NAS. We identify NAS-altered microbial metabolic pathways that are linked to host susceptibility to metabolic disease, and demonstrate similar NAS-induced dysbiosis and glucose intolerance in healthy human subjects. Collectively, our results link NAS consumption, dysbiosis and metabolic abnormalities, thereby calling for a reassessment of massive NAS usage.

Perinatal exposure to perfluorooctane sulfonate affects glucose metabolism in adult offspring.

Wan HT, Zhao YG, Leung PY, Wong CK.

Author information

Abstract

Perfluoroalkyl acids (PFAAs) are globally present in the environment and are widely distributed in human populations and wildlife. The chemicals are ubiquitous in human body fluids and have a long serum elimination half-life. The notorious member of PFAAs, perfluorooctane sulfonate (PFOS) is prioritized as a global concerning chemical at the Stockholm Convention in 2009, due to its harmful effects in mammals and aquatic organisms. PFOS is known to affect lipid metabolism in adults and was found to be able to cross human placenta. However the effects of in utero exposure to the susceptibility of metabolic disorders in offspring have not yet been elucidated. In this study, pregnant CD-1 mice (F0) were fed with 0, 0.3 or 3 mg PFOS/kg body weight/day in corn oil by oral gavage daily throughout gestational and lactation periods. We investigated the immediate effects of perinatal exposure to PFOS on glucose metabolism in both maternal and offspring after weaning (PND 21). To determine if the perinatal exposure predisposes the risk for metabolic disorder to the offspring, weaned animals without further PFOS exposure, were fed with either standard or high-fat diet until PND 63. Fasting glucose and insulin levels were measured while HOMA-IR index and glucose AUCs were reported. Our data illustrated the first time the effects of the environmental equivalent dose of PFOS exposure on the disturbance of glucose metabolism in F1 pups and F1 adults at PND 21 and 63, respectively. Although the biological effects of PFOS on the elevated levels of fasting serum glucose and insulin levels were observed in both pups and adults of F1, the phenotypes of insulin resistance and glucose intolerance were only evident in the F1 adults. The effects were exacerbated under HFD, highlighting the synergistic action at postnatal growth on the development of metabolic disorders.

Chronic Exposure to PCBs (Aroclor 1254) Exacerbates Obesity-Induced Insulin Resistance and Hyperinsulinemia in Mice.

Gray SL, Shaw AC, Gagne AX, Chan HM.

a Northern Medical Program, University of Northern British Columbia , Prince George , British Columbia , Canada.

Abstract

Our results demonstrate a causative association between **PCB** exposure and obesity-induced insulin resistance and hyperinsulinemia independent of body weight changes.

metabolic homeostasis. Chronic exposure of diabetes-prone C57B/6 mice to a polychlorinated biphenyl (PCB) mixture (Aroclor 1254, 36 mg/kg/wk, 20 wk) alone or in combination with high-fat diet impairs carbohydrate metabolism was compared to vehicle-treated control animals. Specifically, PBC exposure was found to produce hyperinsulinemia in both lean and diet-induced obese mice and exacerbated whole-body insulin resistance in obese mice. These changes in carbohydrate metabolism in response to Aroclor 1254 occurred without marked effect on body weight in both lean and obese mice. Our results demonstrate a causative association between PCB exposure and obesity-induced insulin resistance and hyperinsulinemia independent of body weight changes, an observation that contributes to a growing body of evidence suggesting that exposure to environmental pollutants represents a novel risk factor contributing to the diabetes epidemic.

ABSTRACT

Hypercortisolism is associated with insulin resistance (IR) and diabetes mellitus (DM); however, to our knowledge prior studies have not examined the association of diurnal cortisol curve features with measures of glycemia or IR in a population-based setting. Using log-transformed salivary cortisol data on 850 ethnically diverse men and women from the Multi-Ethnic Study of Atherosclerosis, we investigated the cross-sectional association of cortisol curve features with (1) glycemia in those with and without DM and (2) IR, in non-diabetic subjects. The log-transformed salivary cortisol curve features included wake-up cortisol, cortisol awakening response (CAR), early decline slope (30 min to 2 h post-awakening), late decline slope (2 h post-awakening to bedtime), overall decline slope (0 min to bedtime, excluding 30 min cortisol), bedtime cortisol and total area under the curve (AUC). Overall, following multivariable adjustment, among those with diabetes mellitus (DM), early decline slope, overall decline slope, bedtime cortisol, and AUC were significantly and positively associated with a 5.4% (95% CI: 1.3, 9.7), 54.7% (95% CI: 12.4, 112.9), 4.0% (95% CI: 1.6,6.4), and 6.8% (95% CI: 3.3,10.4) higher HbA1c per 1 unit increase in log cortisol feature, respectively. Cortisol curve features were not associated with HbA1c among non-diabetic participants; however, wake-up cortisol and AUC were associated with a 8.2% lower (95% CI: −13.3,−2.7) and 7.9% lower (95% CI: −14.6, −0.6) log HOMA-IR, respectively. This was attenuated by adjustment for waist circumference. Among participants with DM, cortisol curve parameters suggestive of higher hypothalamic-pituitary-adrenal (HPA) axis activity and dysfunction were associated with higher HbA1c. In non-diabetic participants, greater HPA activity was paradoxically associated with lower insulin resistance.

Elevated Intact Proinsulin Levels During an Oral Glucose Challenge Indicate Progressive ß-Cell Dysfunction and May Be Predictive for Development of Type 2 Diabetes.

Pfützner A[1], Hermanns I[2], Ramljak S[3], Demircik F[3], Pfützner AH[4], Kann PH[5], Weber MM[6].

Author information

Abstract

BACKGROUND: Elevated fasting intact proinsulin is a biomarker of late-stage ß-cell-dysfunction associated with clinically relevant insulin resistance. In this pilot investigation, we explored the potential value of measuring intact proinsulin as a functional predictor of ß-cell

Elevated proinsulin is viewed as symptoms of a functionally compromised ß-cell, most often arising from the over-stimulation of chronic hyperglycemia or in later disease stage from therapeutic intervention.

mg/dL, intact proinsulin: 3 ± 2 pmol/L/10 ± 7 pmol/L/10 ± 5 pmol/L); IGT: glucose: 102 ± 9 mg/dL/158 ± 57 mg/dL/149 ± 34 mg/dL, intact proinsulin: 7 ± 4 pmol/L/23 ± 8 pmol/L/28 ± 6 pmol/L; T2DM: glucose: 121 ± 20 mg/dL/230 ± 51 mg/dL/213 ± 34 mg/dL; intact proinsulin: 7 ± 7 pmol/L/26 ± 9 pmol/L/27 ± 10 pmol/L). Five years later, all of the IGT and 2 of the healthy subjects had developed T2DM and one had devloped IGT. All of them had elevated 2-hour proinsulin values in the initial OGTT, while patients with normal intact proinsulin results did not develop diabetes.

CONCLUSIONS: Elevated 2-hour intact proinsulin levels during OGTT were predictive for later type 2 diabetes development. Further studies need to confirm our findings in larger populations.

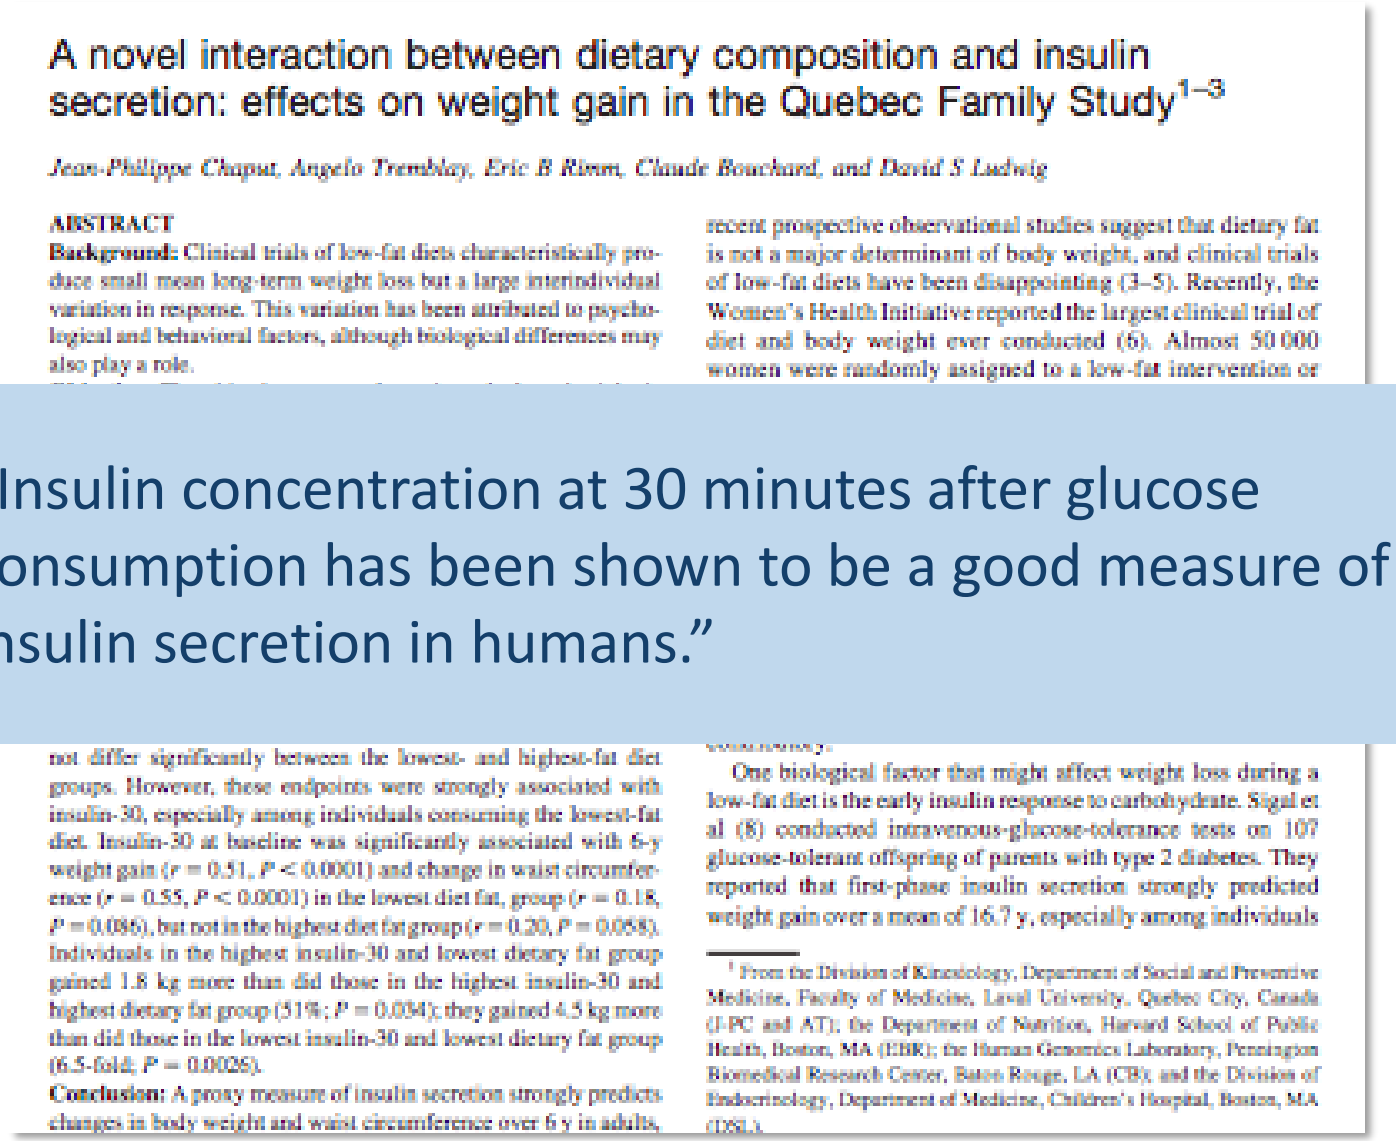
Insulin



A novel interaction between dietary composition and insulin secretion: effects on weight gain in the Quebec Family Study[1–3]

Jean-Philippe Chaput, Angelo Tremblay, Eric B Rimm, Claude Bouchard, and David S Ludwig

ABSTRACT

Background: Clinical trials of low-fat diets characteristically produce small mean long-term weight loss but a large interindividual variation in response. This variation has been attributed to psychological and behavioral factors, although biological differences may also play a role.

recent prospective observational studies suggest that dietary fat is not a major determinant of body weight, and clinical trials of low-fat diets have been disappointing (3–5). Recently, the Women's Health Initiative reported the largest clinical trial of diet and body weight ever conducted (6). Almost 50 000 women were randomly assigned to a low-fat intervention or

not differ significantly between the lowest- and highest-fat diet groups. However, these endpoints were strongly associated with insulin-30, especially among individuals consuming the lowest-fat diet. Insulin-30 at baseline was significantly associated with 6-y weight gain ($r = 0.51$, $P < 0.0001$) and change in waist circumference ($r = 0.55$, $P < 0.0001$) in the lowest diet fat, group ($r = 0.18$, $P = 0.086$), but not in the highest diet fat group ($r = 0.20$, $P = 0.058$). Individuals in the highest insulin-30 and lowest dietary fat group gained 1.8 kg more than did those in the highest insulin-30 and highest dietary fat group (51%; $P = 0.034$); they gained 4.5 kg more than did those in the lowest insulin-30 and lowest dietary fat group (6.5-fold; $P = 0.0026$).

Conclusion: A proxy measure of insulin secretion strongly predicts changes in body weight and waist circumference over 6 y in adults,

One biological factor that might affect weight loss during a low-fat diet is the early insulin response to carbohydrate. Sigal et al (8) conducted intravenous-glucose-tolerance tests on 107 glucose-tolerant offspring of parents with type 2 diabetes. They reported that first-phase insulin secretion strongly predicted weight gain over a mean of 16.7 y, especially among individuals

Circulating leptin and adiponectin are associated with insulin resistance in healthy postmenopausal women with hot flashes.

Huang WY[1], Chang CC[2], Chen DR[3], Kor CT[4], Chen TY[5], Wu HM[5,6,7].

Author information

Abstract

INTRODUCTION: Hot flashes have been postulated to be linked to the development of metabolic disorders. This study aimed to evaluate the relationship between hot flashes, adipocyte-derived hormones, and insulin resistance in healthy, non-obese postmenopausal women.

PARTICIPANTS AND DESIGN: In this cross-sectional study, a total of 151 women aged 45-60 years were stratified into one of three groups according to hot-flash status over the past three months: never experienced hot flashes (Group N), mild-to-moderate hot flashes (Group M), and severe hot flashes (Group S). Variables measured in this study included clinical parameters, hot flash experience, fasting levels of circulating glucose, lipid profiles, plasma insulin, and adipocyte-derived hormones. Multiple linear regression analysis was used to evaluate the associations of hot flashes with adipocyte-derived hormones, and with insulin resistance.

SETTINGS: The study was performed in a hospital medical center.

RESULTS: The mean (standard deviation) of body-mass index was 22.8(2.7) for Group N, 22.6(2.6) for Group M, and 23.5(2.4) for Group S, respectively. Women in Group S displayed statistically significantly higher levels of leptin, fasting glucose, and insulin, and lower levels of adiponectin than those in Groups M and N. Multivariate linear regression analysis revealed that hot-flash severity was significantly associated with higher leptin levels, lower adiponectin levels, and higher leptin-to-adiponectin ratio. Univariate linear regression analysis revealed that hot-flash severity was strongly associated with a higher HOMA-IR index (% difference, 58.03%; 95% confidence interval, 31.00-90.64; $p < 0.001$). The association between hot flashes and HOMA-IR index was attenuated after adjusting for leptin or adiponectin and was no longer significant after simultaneously adjusting for leptin and adiponectin.

CONCLUSION: The present study provides evidence that hot flashes are associated with insulin resistance in postmenopausal women. It further suggests that hot flash association with insulin resistance is dependent on the combination of leptin and adiponectin variables.

In Brief

People eating identical meals present high variability in post-meal blood glucose response. Personalized diets created with the help of an accurate predictor of blood glucose response that

- Using personal and microbiome features enables accurate glucose response prediction
- Prediction is accurate and superior to common practice in an independent cohort
- Short-term personalized dietary interventions successfully lower post-meal glucose

Quantification and Speciation of Mercury and Selenium in Fish Samples of High Consumption in Spain and Portugal

ANA I. CABAÑERO,[1] CRISTINA CARVALHO,[2] YOLANDA MADRID,[1] CAMILA BATORÉU,[2] AND CARMEN CÁMARA[1,*]

Sardines have the best ratio of Selenium/Mercury

Accepted May 31, 2004.

ABSTRACT

Mercury (Hg) and selenium (Se) determinations were carried out to evaluate human exposure to those elements through fish consumption in Spain and Portugal. Atomic fluorescence spectroscopy (AFS) was applied in a cold vapor mode for total mercury quantification and was also hyphenated to gas chromatography (GC) to achieve the speciation of organomercurial species in fish samples. The results obtained show the highest concentration of Hg in swordfish and tuna (0.47 ± 0.02 and 0.31 ± 0.01 μg g^{-1}, respectively), and a much lower concentration in sardine, mackerel shad, and octopus (0.048 ± 0.002, 0.033 ± 0.001, and 0.024 ± 0.001 μg g^{-1}, respectively). The determination of alkyl mercury compounds revealed that 93–98% of mercury in the fish samples was in the organic form. Methylmercury (MeHg) was the only species found in the three fish species with higher mercury content.

Total selenium concentration was high in sardine, swordfish, and tuna (0.43 ± 0.02, 0.47 ± 0.02, and 0.92 ± 0.01 μg g^{-1}, respectively), but low in mackerel shad and octopus (0.26 ± 0.01 and 0.13 ± 0.01 μg g^{-1}, respectively). Speciation of selenium compounds was done by high-performance liquid

lose significant amounts of body weight, reduce their waist circumference and also reduce their glycated haemoglobin level.

BACKGROUND

Type 2 diabetes (T2D) is a chronic disease closely linked to the epidemic of obesity that requires long-term medical attention to limit the development of its wide range of microvascular, macrovascular and neuropathic complications. Many of

preference, ranging from 16 hours to several days. On eating days, patients are encouraged to eat a diet low in sugar and refined carbohydrates, which decreases blood glucose and insulin secretion. The full manual of the dietary regimen used in this study has been published and is quoted in the references.[7]

As such, patients with T2D can reverse their diseases without the worry of side effects and financial burden of many pharmaceuticals, as well as the unknown long-term risks and uncertainty of surgery, all by means of therapeutic fasting.

Abstract in **English**, Spanish

A hypocaloric diet associated with the consumption of microencapsulated fish oil was effective in reducing blood glucose, insulinemia and insulin resistance in women with MS.

placebo group (n = 15) and microencapsulated fish oil group (n = 15) (3 g/day of microencapsulated fish oil containing 0.41 g/day of eicosapentaenoic acid and decosahexaneoic acid). Anthropometric, body composition, clinical and laboratory parameters were assessed before and after the intervention. Paired t-test was used for comparisons within groups and Student's t-test for comparison between groups. We considered $p < 0.05$ as significant values. Results: The comparison between groups revealed a significant reduction of blood glucose, insulinemia and the homeostasis model assessment in the microencapsulated fish oil group after 90 days, as opposed to the placebo group. We also observed reduction of the systolic arterial pressure in the microencapsulated fish oil group. Conclusion: A hypocaloric diet associated with the consumption of microencapsulated fish oil was effective in reducing blood glucose, insulinemia and insulin resistance in women with MS.

Improvement in Glycemic and Lipid Profiles in Type 2

Because low-carbohydrate diets are effective strategies to improve insulin resistance, the hallmark of type 2 diabetes, the purpose of reporting these clinical cases was to reveal the meaningful changes observed in 90 days of low-carbohydrate (LC) ketogenic dietary intervention in female type 2 diabetics aged 18-45. Eleven women (BMI 36.3 kg/m^2) who were recently diagnosed with type 2 diabetes based on HbA1c over 6.5% (8.9%) volunteered to participate in an intensive dietary intervention to limit dietary carbohydrates to under 30 grams daily for 90 days. The main outcome was to determine the degree of change in HbA1c, while secondary outcomes included body weight, blood pressure, and blood lipids. The volunteers lost significant weight (85.7 ± 3.2 kg to 76.7 ± 2.8 kg) and lowered systolic (134.0 ± 1.6 to 123.3 ± 1.1 mmHg) and diastolic (89.9 ± 1.3 to 82.6 ± 1.0 mmHg) blood pressure. HbA1c dropped to 5.6%. Most blood lipids were significantly altered, including HDL cholesterol (43.1 ± 4.4 to 52.3 ± 3.3 mg/dl), triglycerides (177.0 ± 19.8 to 92.1 ± 8.7 mg/dl), and the TG : HDL ratio (4.7 ± 0.8 to 1.9 ± 0.2). LDL cholesterol was not significantly different. AST and ALT, plasma markers of liver health, were reported for eight patients and revealed no significant changes. These findings indicate that a short-term intervention emphasizing protein and fat at the expense of dietary carbohydrate functionally reversed the diabetes diagnosis, as defined by HbA1c. Furthermore, the intervention lowered body

"These findings indicate that a short-term intervention emphasizing protein and fat at the expense of dietary carbohydrate functionally reversed the diabetes diagnosis, as defined by HbA1c. Furthermore, the intervention lowered body weight and blood pressure, while eliciting favorable changes in blood lipids."

REVIEW

Obesity and the gut microbiota: does up-regulating colonic fermentation protect against obesity and metabolic disease?

Lorenza Conterno · Francesca Fava · Roberto Viola · Kieran M. Tuohy

"Most studies suggest that the gut microbiota differs in composition between lean and obese individuals and that diet, especially the high-fat low-fiber Western-style diet, dramatically impacts on the gut microbiota."

hand, the adoption of "western"-style diets and low-energy expenditure lifestyles around the world. Recent studies report an aberrant gut microbiota in obese subjects and that gut microbial metabolic activities, especially carbohydrate fermentation and bile acid metabolism, can impact on a number of mammalian physiological functions linked to obesity. The aim of this review is to present the evidence for a characteristic "obese-type" gut microbiota and to discuss studies linking microbial metabolic activities with mammalian regulation of lipid and glucose metabolism, thermogenesis, satiety, and chronic systemic inflammation. We focus in particular on short-chain fatty acids (SCFA) produced upon fiber fermentation in the colon. Although SCFA are reported to be elevated in the feces of

dietary modulation of associated disease risk.

Introduction

Obesity is now considered among the top public health issues worldwide. In many countries, obesity rates reported before 1980 were below 10%, whereas nearly half of the Organization for Economic Co-operation and Development (OECD) countries now report 50% or more of the population as being overweight, with the percentage obese

during chronic or intermittent dietary fiber deficiency, the gut microbiota resorts to host-secreted mucus glycoproteins as a nutrient source, leading to erosion of the colonic mucus barrier. Dietary fiber deprivation, together with a fiber-deprived, mucus-eroding microbiota, promotes greater epithelial access and lethal colitis by the mucosal pathogen, Citrobacter rodentium. Our work reveals intricate pathways linking diet, the gut microbiome, and intestinal barrier dysfunction, which could be exploited to improve health using dietary therapeutics.

Abstract

Although probiotics and antibiotics have been used for decades as growth promoters in animals, attention has only recently been drawn to the association between the gut microbiota composition, its manipulation, and obesity. Studies in mice have associated the phylum *Firmicutes* with obesity and the phylum *Bacteroidetes* with weight loss. Proposed mechanisms linking the microbiota to fat content and weight include differential effects of bacteria on the efficiency of energy extraction from the diet, and changes in host metabolism of absorbed calories. The

The microbiota can be manipulated by prebiotics, probiotics, and antibiotics. Probiotics affect the microbiota directly by modulating its bacterial content, and indirectly through bacteriocins produced by the probiotic bacteria.

Introduction

The risk of developing obesity rises with a Westernized lifestyle. In industrialized and developing countries obesity contributes to increased mortality by predisposing to serious pathological conditions such as type 2 diabetes, cardiovascular disease, fatty liver, arthritis, asthma, and neoplasia [1–2]. Clinical and

IL-1, IL-6, IL-17, and monocyte chemoattractant protein-1 (MCP-1) have been reported to contribute to obesity-associated pathologies. In parallel, regulatory T cells down-regulate host inflammatory responses [2-3,6–10].

It is well documented that "fast food" with high fat and salt content at relatively low cost is a major cause of the obesity epidemic in Western societies. Recent epidemiological research

Effect of *Lactobacillus gasseri* BNR17 on Overweight and Obese Adults: A Randomized, Double-Blind Clinical Trial

Original Article

Seung-Pil Jung*, Keun-Mi Lee, Ji-Hee Kang[1], Sung-Il Yun[1], Han-Oh Park[1], Yong Moon[2], Jong-Yeon Kim[3]

participated in a placebo controlled, randomized, and double-blind trial. For 12 weeks, 57 participants were given either placebo or BNR17 and were tested by measuring body fat, body weight, various biochemical parameters, vital signs, and computed tomography at the start of the study and at weeks 4, 8, and 12. The subjects assumed usual daily activities without having to make behavioral or dietary modifications during the course of the study.

Results: At the 12th week, a slight reduction in body weight was noted in the BNR17 group, but there were no significant weight changes between groups. Decrease of waist and hip circumferences in the BNR17 group was more pronounced than those in the placebo group. The two groups had no special or severe adverse reactions.

Conclusion: Despite there being no change in behavior or diet, administration of only the supplement of BNR17 reduced weight and waist and hip circumference. However, there were no significant differences between the two groups. These findings warrant a subsequent longer-term prospective clinical investigation with a large population.

Lactobacillus casei reduces susceptibility to type 2 diabetes via microbiota-mediated body chloride ion influx

SUBJECT AREAS:
CHRONIC INFLAMMATION
NUTRITION

Received

GlyRα1, SLC26A3, SLC26A6, GABAAα1, Beistrophin-3 and *CFTR*). A shift in the caecal microflora, particularly the reduction of bile acid 7α-dehydroxylating bacteria, and fecal bile acid profiles also occurred. These change coincided with organ chloride influx. Thus, we postulate that the prevention of T2DM onset by *L. casei* Zhang may be via a microbiota-based bile acid-chloride exchange mechanism.

Obesity associated T2DM has drawn much scientific attention, as evident by the rapidly increasing number of published investigations. Data showed that the world population is facing a surge in T2DM as well as individuals with prediabetes due to rapid change in lifestyle[1]. Thus, both strategies for both the prevention and treatment of diabetes are needed, especially in the dietary aspect.

Diet is directly associated with intestinal microbiota. There is a growing interest in understanding the changes of gut microbiota in the context of diabetes. In recent years, metagenomics has opened a new era of microbial ecology that has allowed deeper understanding of microbiome associated hyperglycemia[2,3]. On the other hand, it is proposed that high-fat diet induces a low-grade inflammation through modifying microflora and thus increases lipopolysaccharides (LPS) and in turn triggers the development of metabolic diseases[4]. More interestingly, commensal microbiota and related bile acids profile could be rapidly reshaped by dietary alteration[5], but how the pathogenesis of T2DM relates with the interaction between bile acids and chloride ion is rarely studied. This aspect is of particular interest because both bile acids and choride ions can acted as regulating signaling molecules for metabolic homeostasis[6,7].

Several studies have also shown that probiotic products could regulate the blood glucose level in diabetic human[8,9]. Moreover, *L. casei* Shirota has been reported to reduce blood glucose level through reducing lipopo-

ARTICLE INFO

Article history:

ABSTRACT

Objective: Metabolic syndrome (MetS) in postmenopausal women is an important risk factor for

biomarkers were measured.

Results: Total cholesterol and γ-glutamyltranspeptidase had a significant reduction both in NFM ($P = 0.043$ and $P = 0.036$, respectively) and FM groups ($P = 0.010$ and $P = 0.018$, respectively) after 90 d, whereas low-density lipoprotein cholesterol showed a significant reduction in NFM group ($P = 0.002$) and trend in the FM group ($P = 0.092$). Glucose and homocysteine levels showed a significant reduction in the FM group compared with the NFM group ($P = 0.037$ and $P = 0.019$, respectively). In relation to inflammatory biomarkers, there was a significant decrease in interleukin-6 both in NFM ($P = 0.032$) and in FM ($P = 0.001$) groups.

Conclusion: FM with *L. plantarum* showed more favorable results than NFM in relation to cardiovascular risk factors in postmenopausal women with MetS.

Introduction

Metabolic syndrome (MetS) is a pathologic condition that includes insulin resistance, arterial hypertension, obesity, and dyslipidemia, which accelerate atherosclerosis, and promote a higher risk for cardiovascular disease (CVD) [1]. MetS also has been considered a chronic low-grade inflammatory syndrome [2]. The prevalence of MetS rises with increasing age, which is mainly attributed to the significant increase in overweight and obesity [3].

Previous human studies have found some beneficial effects of *Lactobacillus* species in reducing adiposity in overweight

An increase in the Akkermansia spp. population induced by metformin treatment improves glucose homeostasis in diet-induced obese mice.

Shin NR[1], Lee JC, Lee HY, Kim MS, Whon TW, Lee MS, Bae JW.

Author information

"Modulation of the gut microbiota (by an increase in the *Akkermansia* spp. population) may contribute to the antidiabetic effects of metformin, thereby providing a new mechanism for the therapeutic effect of metformin in patients with T2D."

Adipose tissue inflammation was examined by flow cytometric analysis of the immune cells present in visceral adipose tissue (VAT).

RESULTS: Metformin treatment significantly improved the glycaemic profile of HFD-fed mice. HFD-fed mice treated with metformin showed a higher abundance of the mucin-degrading bacterium Akkermansia than HFD-fed control mice. In addition, the number of mucin-producing goblet cells was significantly increased by metformin treatment ($p<0.0001$). Oral administration of Akkermansia muciniphila to HFD-fed mice without metformin significantly enhanced glucose tolerance and attenuated adipose tissue inflammation by inducing Foxp3 regulatory T cells (Tregs) in the VAT.

CONCLUSIONS: Modulation of the gut microbiota (by an increase in the Akkermansia spp. population) may contribute to the antidiabetic effects of metformin, thereby providing a new mechanism for the therapeutic effect of metformin in patients with T2D. This suggests that pharmacological manipulation of the gut microbiota in favour of Akkermansia may be a potential treatment for T2D.

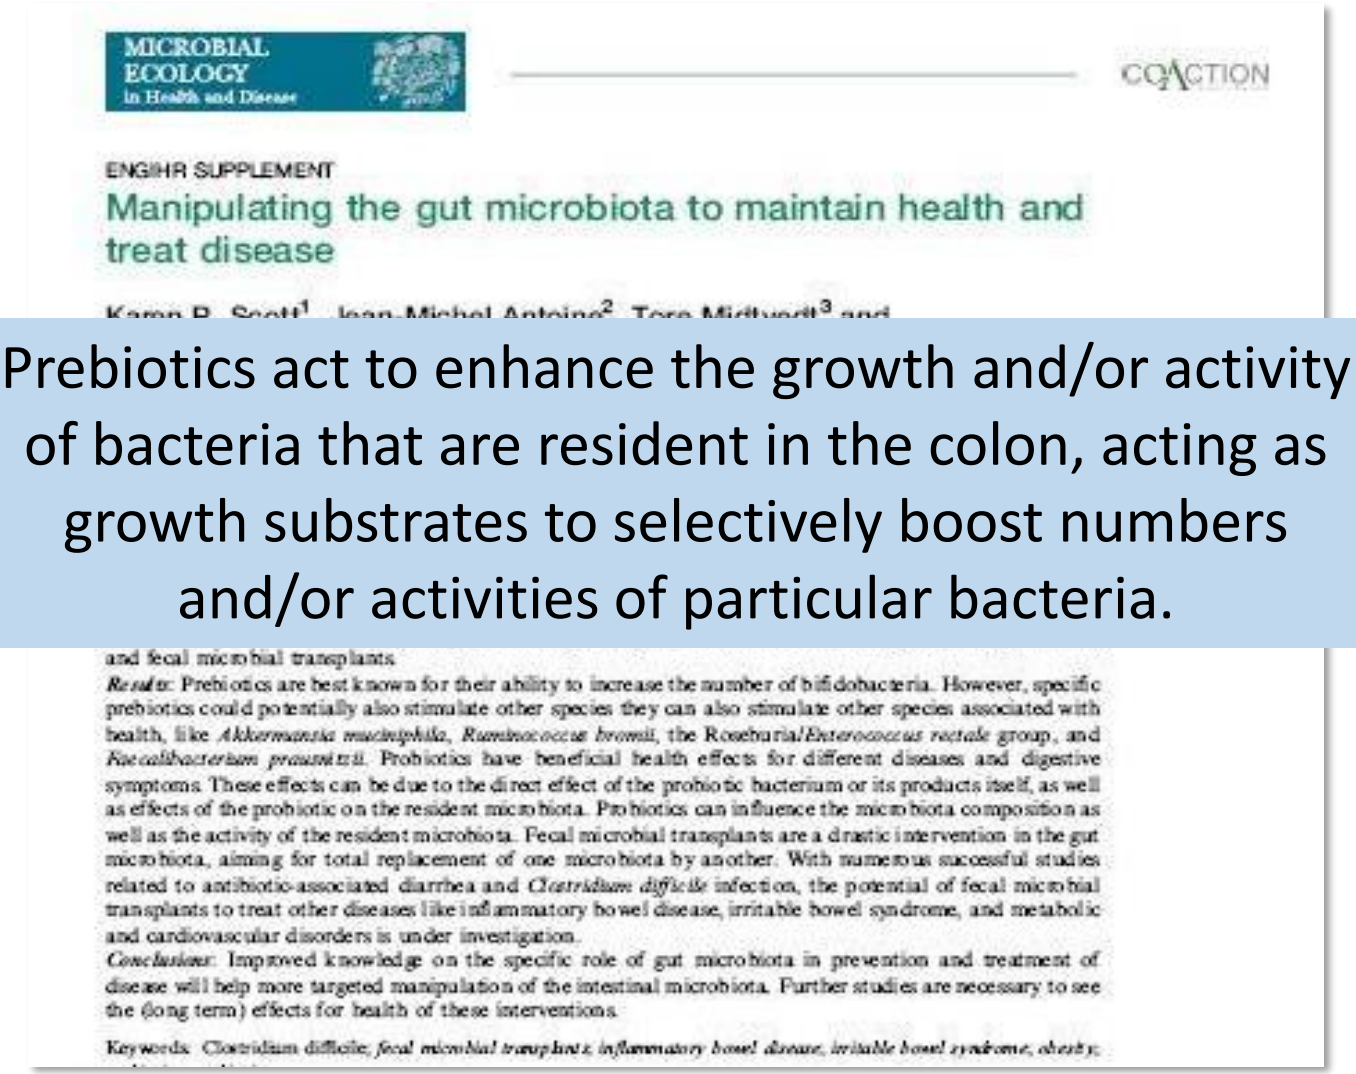
Gut Microbiota



MICROBIAL ECOLOGY in Health and Disease

COACTION

ENGIHR SUPPLEMENT

Manipulating the gut microbiota to maintain health and treat disease

Karen P. Scott[1], Jean-Michel Antoine[2], Tore Midtvedt[3] and

Prebiotics act to enhance the growth and/or activity of bacteria that are resident in the colon, acting as growth substrates to selectively boost numbers and/or activities of particular bacteria.

and fecal microbial transplants.

Results: Prebiotics are best known for their ability to increase the number of bifidobacteria. However, specific prebiotics could potentially also stimulate other species they can also stimulate other species associated with health, like *Akkermansia muciniphila*, *Ruminococcus bromii*, the Roseburia/*Enterococcus rectale* group, and *Faecalibacterium prausnitzii*. Probiotics have beneficial health effects for different diseases and digestive symptoms. These effects can be due to the direct effect of the probiotic bacterium or its products itself, as well as effects of the probiotic on the resident microbiota. Probiotics can influence the microbiota composition as well as the activity of the resident microbiota. Fecal microbial transplants are a drastic intervention in the gut microbiota, aiming for total replacement of one microbiota by another. With numerous successful studies related to antibiotic-associated diarrhea and *Clostridium difficile* infection, the potential of fecal microbial transplants to treat other diseases like inflammatory bowel disease, irritable bowel syndrome, and metabolic and cardiovascular disorders is under investigation.

Conclusions: Improved knowledge on the specific role of gut microbiota in prevention and treatment of disease will help more targeted manipulation of the intestinal microbiota. Further studies are necessary to see the (long term) effects for health of these interventions.

Abstract

BACKGROUND & A … 2 diabetes mellitus.

SUBJECTS AND ME … non diabetic controls. A specifica… es. The speed of eating was self-repo… The odds ratios (OR), and 95% conf…

More than two-fold increased risk of type 2 diabetes was determined for subjects eating faster vs. subjects eating slower.

RESULTS: Variables such as a family history on diabetes, body mass index, waist circumference, educational level, morning exercise, smoking and plasma triglycerides level were retained in multivariate logistic regression models as confounders because their inclusion changed the value of the OR by more than 5% in any exposure category. After adjustment for possible confounders more than two-fold increased risk of type 2 diabetes was determined for subjects eating faster (OR = 2.52; 95% CI 1.56-4.06) vs. subjects eating slower.

CONCLUSIONS: Our data support a possible relationship between faster eating speed and the increased risk of type 2 diabetes mellitus.

Drinking one 12-ounce sugar sweetened soft drink a day can increase the risk of type 2 diabetes by 22%

participants selected from eight European cohorts participating in the European Prospective Investigation into Cancer and Nutrition (EPIC) study. After exclusions, the final sample size included 11,684 incident cases and a subcohort of 15,374 participants. Cox proportional hazards regression models (modified for the case-cohort design) and random-effects meta-analyses were used to estimate the association between sweet beverage consumption (obtained from validated dietary questionnaires) and type 2 diabetes incidence.

RESULTS: In adjusted models, one 336 g (12 oz) daily increment in sugar-sweetened and artificially sweetened soft drink consumption was associated with HRs for type 2 diabetes of 1.22 (95% CI 1.09, 1.38) and 1.52 (95% CI 1.26, 1.83), respectively. After further adjustment for energy intake and BMI, the association of sugar-sweetened soft drinks with type 2 diabetes persisted (HR 1.18, 95% CI 1.06, 1.32), but the association of artificially sweetened soft drinks became statistically not significant (HR 1.11, 95% CI 0.95, 1.31). Juice and nectar consumption was not associated with type 2 diabetes incidence.

CONCLUSIONS/INTERPRETATION: This study corroborates the association between increased incidence of type 2 diabetes and high consumption of sugar-sweetened soft drinks in European adults.

Laughter and Diabetes

Laughter lowered the increase in postprandial blood glucose.

In 19 **diabetic patients,** (mean age 63, mean BMI 23.5, mean HbA1c 7.2, not on insulin) the mean **blood sugar 2 hr after a 500 kcal meal rose 121 mg/dl above FBS in those who had attended a 40 minute dry lecture vs. a rise of 77 mg/dl after attending a comedy show during which their laughter level was 4-5/5**.

Exercise

- Alters skeletal muscle metabolism and improves glucose uptake
- Reduces low-density lipoprotein, raises HDL
- Lowers blood pressure
- Reduces inflammation and oxidative stress

Importance of Lifestyle

- *Diabetes Prevention Program Research Group* – 2002 study
- 3234 prediabetics were randomized to placebo, metformin, or lifestyle modification (≥7% weight loss and ≥150 min/wk of physical activity) for 2.8 years
- Results: Compared to placebo:
  - Lifestyle intervention decreased incidence of type 2 DM by 58%
  - Metformin decreased type 2 DM by only 31%

Inadequate sleep as a contributor to type 2 diabetes in children and adolescents.

Dutil C[1], Chaput JP[1].

Author information

Abstract

There is a link between inadequate sleep and type 2 diabetes in children and adolescents.

studies). Notwithstanding the conflicting results found in these studies and despite being attenuated by adiposity level, maturity, sex and age, there is still some compelling evidence for an association between sleep duration (for both objective or subjective measurements of duration) and architecture with one or more T2D biomarkers in children and adolescents. The majority of the studies reviewed did focus on sleep duration and one or more T2D biomarkers in children and adolescents, but sleep architecture, more precisely the suppression of slow wave sleep and rapid eye movement sleep, has also been shown to be associated with insulin resistance. Only two studies looked at sleep quality, and the association between sleep quality and insulin resistance was not independent of level of adiposity. Future experimental studies will help to better understand the mechanisms linking insufficient sleep with T2D. Work also needs to be carried out on finding novel and effective strategies aimed at improving sleep hygiene and health outcomes of children and adolescents.

Effect of probiotic (VSL#3) and omega-3 on lipid profile, insulin sensitivity, inflammatory markers, and gut colonization in overweight adults: a randomized, controlled trial.

Rajkumar H[1], Mahmood N[1], Kumar M[1], Varikuti SR[1], Challa HR[1], Myakala SP[1].

Author information

Abstract

Addition of omega-3 fatty acid with VSL#3 had more pronounced effect on HDL, insulin sensitivity and hsCRP.

groups received, respectively, placebo, omega-3 fatty acid, probiotic VSL#3, or both omega-3 and probiotic, for 6 weeks. Blood and fecal samples were collected at baseline and after 6 weeks. The probiotic (VSL#3) supplemented group had significant reduction in total cholesterol, triglyceride, LDL, and VLDL and had increased HDL ($P < 0.05$) value. VSL#3 improved insulin sensitivity ($P < 0.01$), decreased hsCRP, and favorably affected the composition of gut microbiota. Omega-3 had significant effect on insulin sensitivity and hsCRP but had no effect on gut microbiota. Addition of omega-3 fatty acid with VSL#3 had more pronounced effect on HDL, insulin sensitivity and hsCRP. Subjects with low HDL, insulin resistance, and high hsCRP had significantly lower total lactobacilli and bifidobacteria count and higher E. coli and bacteroides count.

Nutrients Known to Modify Insulin Responsiveness

- Chromium
- Alpha-lipoic acid
- CoQ10
- Vitamin D
- Magnesium
- Vitamin C, vitamin E and other antioxidants
- Omega 3 fatty acids
- Curcumin
- Vanadium
- Serum kinase receptor modulators (SKRMs)

Magnesium

- Epidemiological studies show that high daily Mg intake is predictive of a lower incidence of NIDDM
- Poor intracellular Mg concentration are found in NIDDM and in hypertensive patients
- Daily Mg administration in NIDDM patients and in insulin resistant patients restores intracellular Mg concentration and contributes to improves insulin sensitivity and glucose uptake

"The results of this study indicate that **higher dietary magnesium intake is strongly associated with the attenuation of insulin resistance** and is more beneficial for overweight and obese individuals in the general population and pre-menopausal women. Moreover, **the inverse correlation between insulin resistance and dietary magnesium** intake is stronger when adjusting for %BF than BMI."

HOMA-ß and subjects with the lowest intake of dietary magnesium had the highest levels of these measures, suggesting a dose effect. Multiple regression analysis revealed a strong inverse association between dietary magnesium with IR. In addition, adiposity and menopausal status were found to be critical factors revealing that the association between dietary magnesium and IR was stronger in OW and OB along with Pre-menopausal women.

Conclusion: The results of this study indicate that higher dietary magnesium intake is strongly associated with the attenuation of insulin resistance and is more beneficial for overweight and obese individuals in the general population and pre-menopausal women. Moreover, the inverse correlation between insulin resistance and dietary magnesium intake is stronger when adjusting for %BF than BMI.

Micronutrient Recommendations

- Chromium: If using generally give 200mcg/daily if insulin resistant. Likely most effective if deficient, but difficult to test.
- Vitamin D: Test 25(OH)D and supplement as appropriate (or supplement 2000-5000) IU/daily
- Magnesium: Generally give 200-400 mg. Likely most effective if deficient, accurate testing is cumbersome. Supplementation if signs and symptoms of deficiency/insufficiency.
- CoQ10 100-200 mg/day: Generally supplement in patients with metabolic syndrome or diabetes if also hypertensive.
- Alpha lipoic acid: 600 mg bid if diabetic or specifically if have peripheral neuropathy. Likely useful at lower dosages in insulin resistant.
